

High performance TX spherical plain bearings and rod ends

Maintenance-free plain bearing solutions from SKF

- Extremely robust for heavy-duty applications
- Extremely wear-resistant for longer service life
- Totally maintenance-free – everywhere

A maintenance-free world

The challenge

Today there is an increasing need to provide bearing solutions that will minimize maintenance and consume less lubricant while increasing bearing service life. To meet this challenge and future demands, SKF has developed TX spherical plain bearings and rod ends.

This line of bearings and rod ends represents a new level of performance for maintenance-free spherical plain bearings.

Available in either through-hardened or stainless steel, TX spherical plain bearings are characterized by the following

- improved PTFE fabric
- stronger, more efficient seals
- optimized contact surfaces.

Each of these improvements has had an impact on the ability of the bearing to accommodate heavier loads and last longer even in contaminated environments.

The advantage of increased load capability is that the bearings can accommodate heavier loads in the same or even smaller space than previous maintenance-free designs. This opens the door to down-sizing options that have not been available until now.

And because TX spherical plain bearings do not rely on traditional oil-based lubricants that require relubrication, these bearings are an “environmentally friendly” alternative when compared to traditional plain bearing designs.

TX spherical plain bearings are in a performance class of their own. Their unique features include

- an optimized and stronger PTFE fabric liner with high wear-resistance
- stronger high-performance seals
- superfinished or hard chromium plated sliding contact surfaces
- bearing rings of through-hardened or stainless steel.

Application areas

Extended service life, increased reliability and maintenance-free operation are the major advantages of these high-performance TX spherical plain bearings and rod ends.

In addition to the applications listed on the right, these bearings and rod ends can be used wherever spherical plain bearings and rod ends are normally used.

- Dam gates
- Hydraulic cylinders
- Stabilizers
- Cranes
- Conveyor chains
- Forestry machinery
- Industrial robots
- Textile and printing machinery
- Machines for the food industry
- Automotive applications
- Wind turbine rotor blades
- Structural rods of all types.

Improvements provide longer service life

Optimized PTFE fabric

The SKF PTFE liner (→ **fig. 1**) is what gives the TX bearing its performance characteristics. Both the structure of this self-lubricating fabric and the resin have been improved to make TX bearings stronger than previous designs.

But it is not just the sliding surface that has been improved. The bonding agent has also been improved to provide better adhesion to the hardened surface of the outer ring. This bonding agent is three times stronger than previous formulas.

The SKF PTFE liner also provides the following benefits

- greater stiffness, resulting in less deformation under load
- better wear-resistance for increased service life
- excellent frictional behaviour, thus simplifying the design of the bearing arrangement
- low affinity to moisture, which provides water repellent properties.

Strong seals

TX spherical plain bearings are equipped with high-performance LS seals so that the bearing can achieve maximum service life even under contaminated conditions.

The high-performance LS seal has three sealing lips that exert pressure on the counter-face of the inner ring to protect the bearing against contaminants and moisture (→ **fig. 2**).

To keep the seal firmly in place, it contains a robust sheet steel reinforcement. This sheet steel “backbone” provides mechanical stability as it protects the elastomer against damage from coarse contaminants.

For large-size bearings where LS seals are not available, the RS double-lip seal is used.

Sliding contact surfaces

The sphered convex surface of the through-hardened inner ring is ground and polished before it is chromium plated. This enhances the transfer of PTFE from the TX fabric liner to the counter surface during a brief running in phase. It is a requisite to provide characteristically low friction and low wear in operation.

Available in stainless steel too

For normal operating conditions, SKF TX spherical plain bearings made from steel for through hardening are the best choice. However, in corrosive environments, the use of stainless steel bearings may be more cost-effective when total costs or the service life of the machine are taken into account.

So, where TX spherical plain bearings are involved, there is no need to compromise.

In line with trends

Increased load carrying capacity

Both the dynamic and static load carrying capacity of the TX liner have been increased when compared to the old T liner (→ **diagram 1**). This provides design engineers with any one of the following options

- increase service life of existing designs
- maintain power output of down-sized designs
- replace steel-on-steel spherical plain bearings with maintenance-free TX bearings.

Improved reliability, the opportunity to down-size and maintenance-free operation are just three more reasons to take a closer look at SKF TX spherical plain bearings and rod ends.

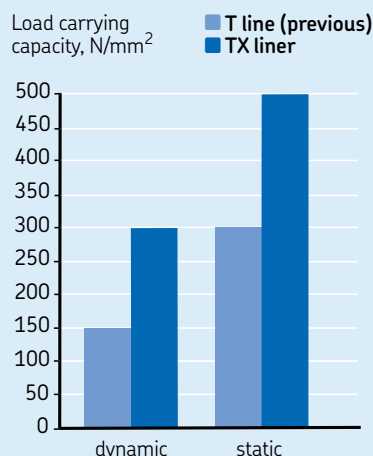

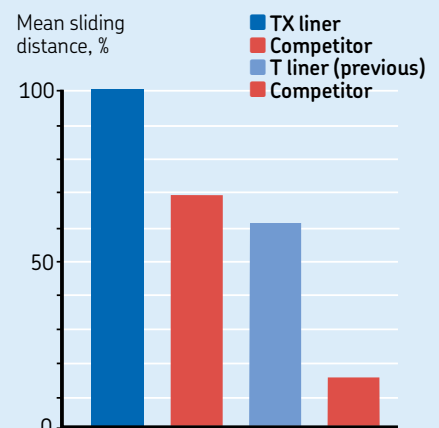

Diagram 2

Extended service life of TX spherical plain bearings

Extended service life

When compared to competitive products and the previous SKF design, TX spherical plain bearings had a significantly longer service life (→ **diagram 2**). The extra sliding distance that the bearings provide means increased service life and reliability for machine designers and end users alike.

Expanded operating range

The TX line of spherical plain bearings can not only accommodate heavier loads, they can also achieve higher sliding velocities than previous designs (→ **diagram 3**). These improved operating parameters enable design engineers to use maintenance-free TX spherical plain bearings where it may not have been possible before.

Profit from our knowledge

Now you can add value to your products with maintenance-free TX spherical plain bearings from SKF. Your customers will be able to see that their applications are providing increased service life and that maintenance-free really does mean “fit and forget”.

But don't forget – performance comes at a price. And when you look at the price/performance ratio, you will see that TX spherical plain bearings can substantially reduce

system costs – making them a very cost-effective alternative to other plain bearing designs.

A complete range of maintenance-free solutions

The bore diameter of TX spherical plain bearings in the GE series range from 12 to 300 mm. These bearings, which cover the most popular sizes, are available in through-hardened as well as stainless steel.

In addition, TX spherical plain bearings are also available in the following series

- GEH series radial bearings with a larger angle of tilt (→ **fig. 3**)
- GEZ inch series radial bearings (→ **fig. 4**)
- GEC series radial bearings with a bore diameter greater than 300 mm
- GAC series angular contact spherical plain bearings (→ **fig. 5**)
- GX series spherical plain thrust bearings (→ **fig. 6**).

Selection of bearing size

Basic rating life

Due to their enhanced performance characteristics, the basic rating life calculation method used for TX spherical plain bearings has been revised. The basic rating life calculation method takes into account the life improvements made to the bearings. The equation is

$$G_h = b_1 b_2 b_4 \frac{K_p}{p^n v}$$

where

G_h = basic rating life, operating hours

b_1 = load direction factor (→ **table 1**)

b_2 = temperature factor (→ **diagram 4**)

b_4 = velocity factor (→ **diagram 5**)

p = specific bearing load, N/mm²

K_p = constant for the specific bearing load (→ **table 2**)

n = exponent for the specific bearing load (→ **table 2**)

v = mean sliding velocity, m/s

Requisite size

To determine the requisite bearing size it is necessary to know the basic rating life required for the actual application. This normally depends on the type of machine, the operating conditions and the demands regarding operational reliability.

As a first approximation a guideline value for the load ratio C/P of 2 can be used to obtain the requisite basic dynamic load rating C for TX spherical plain bearings and rod ends.

The suitability of a bearing or rod end for a particular load and sliding velocity can then be checked using **diagram 3**. The values of the equivalent dynamic bearing load P , the specific bearing load p and the mean sliding velocity v needed to do this can be determined using the equations below.

If the bearing is found to be suitable then the basic rating life can be calculated using the life equation shown above.

Equivalent dynamic bearing load

TX radial spherical plain bearings can accommodate some axial load F_a in addition to a simultaneously acting radial load F_r (→ **fig. 7**). The equivalent dynamic bearing load can be obtained from

$$P = y F_r$$

where

P = equivalent dynamic bearing load, kN

F_r = radial component of the load, kN

y = axial load factor according to **diagram 6**

Specific bearing load

The specific bearing load can be calculated using

$$p = 300 \frac{P}{C}$$

where

p = specific dynamic bearing load, N/mm²

P = equivalent dynamic bearing load, kN

C = basic dynamic load rating, kN

If the load acts radially only, the load $P = F_r$ can be inserted in the equation to calculate the specific bearing load.

Mean sliding velocity

Where movement is continuous the mean sliding velocity can be calculated from

$$v = 5,82 \times 10^{-7} d_k \beta f$$

where

v = mean sliding velocity, m/s

d_k = sphere diameter of the inner ring, mm

β = half angle of oscillation (→ **fig. 8**), degrees (for rotation, $\beta = 90^\circ$)

f = frequency of oscillation, min⁻¹, or rotational speed, r/min

Designs

TX spherical plain bearings are, depending on size and material, available in the following designs:

TXE-2LS

This bearing has rings that are through-hardened and ground. The inner ring has a hard chromium plated sliding surface. The outer ring, which is purposely fractured at one position, contains the TX fabric liner and is fitted with heavy-duty LS seals (→ **fig. 9**).

TXA-2LS and TXA-2RS

Like the TXE-2LS, these bearings have rings that are through-hardened and ground. The inner ring sliding surface has been plated with hard chromium. The outer ring, which contains the TX fabric liner, is split axially and held together by a band inserted in a groove. Smaller sizes are fitted with LS high performance triple lip seals (→ **fig. 10**), larger bearings have RS double lip seals.

TXGR

This stainless steel bearing combines a hardened X46Cr13 inner ring that has a superfinished sliding surface with an unhardened X17CrNi16-2 outer ring. The outer ring is pressed around the inner ring and is not fractured (→ **fig. 11**).

TXG3E-2LS

The stainless steel X46Cr13 rings for this bearing are hardened and ground. The inner ring has a superfinished sliding surface. The outer ring, which is purposely fractured at one position, contains the TX fabric liner and heavy-duty LS seals (→ **fig. 9**).

TXG3A-2LS and TXG3A-2RS

The stainless steel X46Cr13 rings for this bearing are hardened and ground. The inner ring has a superfinished sliding surface. The outer ring, which contains the TX fabric liner, is split axially and held together by a band inserted in a groove. Smaller sizes are fitted with LS high performance seals (→ **fig. 10**), larger bearings have RS double lip seals.

Rod ends

SKF rod ends consist of a cast iron housing that contains a standard TXE-2LS spherical plain bearing (→ **fig. 12**). Rod ends are available with a right or left hand, male (**a**) or female (**b**) thread.

¹⁾ Dynamic load rating of the bearing to be used for basic rating life calculation only. Check suitability of the rod end against its static load rating in all cases.
The dynamic load applied on the rod end must not exceed its static load rating

²⁾ Rod ends with a left hand thread are identified by the additional designation prefix L, e.g. SALA 50 TXE-2LS or SAL 50 TXE-2LS

Always the best choice

SKF maintenance-free spherical plain bearings are an excellent choice when reducing friction, decreasing environmental impact and cost-effective design are all important considerations. In addition to TX spherical plain bearings, SKF offers a wide range of maintenance-free plain bearings and rod ends, including two additional types of dry sliding contact surface combinations.

Maintenance free spherical plain bearings with a sintered bronze composite against a hard chromium surface – GE .. C and GE .. CJ2 series
Suitable for applications where there are moderate to heavy loads, where low friction and insensitivity to misalignment are required.

Maintenance-free spherical plain bearings with a PTFE composite against a hard chromium or steel surface – GEC .. FBASA and GEP .. FS series
Suitable for severe applications where there are heavy loads and where low friction and insensitivity to misalignment are required.

Maintenance-free angular contact spherical plain bearings with a PTFE composite against a hard chromium surface – GAC .. F series

Particularly suitable for applications where there are combined (radial and axial) loads; where loads may be heavy and in one direction and where re-lubrication is not possible or desirable.

Maintenance-free spherical plain thrust bearings with a PTFE composite against a hard chromium surface – GX .. F series

Suitable for applications where there are heavy axial loads in one direction, where low friction and insensitivity to misalignment are required.

Maintenance-free rod ends with a sintered bronze composite against a hard chromium surface – SI .. C and SA .. C series

Suitable for applications where there are moderate loads acting in one direction, even at high temperatures, and where low friction and insensitivity to misalignment are required.

Maintenance-free rod ends with a PTFE composite against a hard chromium surface – SIKB .. F and SAKB .. F series

Suitable for applications where there are moderate loads acting in one direction, and where low friction and insensitivity to misalignment are required and where high temperatures are not an issue.

PTFE composite bushings – PCM .. E and PCMF .. E series

Bushings with a PTFE composite dry sliding material have good dimensional stability and thermal conductivity and provide smooth, low-friction operation without lubrication and maintenance.

Thrust washers and strips – PCMW and PCMS series

Suitable for thrust bearing arrangements that have to perform oscillating or slow rotational movements; where axial space is extremely limited; where freedom from maintenance is required.

Stainless steel backed composite bushings – PI series

Completely self-lubricating bushings that can accommodate heavy loads under low sliding velocity conditions in a corrosive environment.

Filament wound bushings – PWM series

Maintenance-free and corrosion-resistant high-performance bushings for applications where heavy loads and vibrations occur and where maintenance-free operation is preferred.

Sintered bronze bushings – PSM and PSMF series

Bushings consisting of sintered metallic bronze matrix with fully impregnated pores. Most suitable for applications with rotating movements and where self-lubricating properties are required.
